

A method of recognizing and indexing documents

Field of the Invention

The present invention relates to the scientific field of recognizing and indexing documents in a database. It provides more particularly apparatus and
5 a corresponding method enabling technical drawings and forms to be indexed by recognizing only some of their elements.

Background art

There are many methods of recognizing documents that are well known. They make use of an initial scanning step followed by a segmentation step in
10 turn followed by an optical character recognition (OCR) step. The segmentation step (subdividing the document) can be applied to the entire document (a conventional "full page") or to part of the document only.

Nevertheless, such a conventional method making it subsequently possible to index the document automatically can be envisaged only if the
15 document to be recognized is not too complex. In addition, it is not applied to technical drawings. In this particular field, only the initial step of scanning is performed, with the steps of segmentation and recognition being replaced by a step that is performed directly by an operator and consisting in manually inputting the particular elements required for indexing the drawing, from one or
20 more zones of the drawing (in practice present in the title block of the drawing).

It will be understood that under such circumstances, this becomes very tedious when it is necessary to index more than a dozen technical drawings, possibly of different types (i.e. with information blocks of different shapes). There thus exists, at present, an unsatisfied need for a method of indexing such
25 drawings on the basis of automatic recognition.

Summary of the invention

The invention thus proposes resolving this problem in a manner that is simple and of low cost by implementing a method of recognizing and indexing documents using a scanner connected to a computer, the method including
30 scanning the documents, then using a pointing device or member of the

identified automatically without some arbitrary point P of the box being designated beforehand.

The databases can be integrated in the memory of the computer or they can be external thereto. The pointing device or member can be replaced by the keyboard of the computer or by the finger of the user.

Advantages of the present invention will become more apparent from the detailed description given hereinafter. However, it should be understood that the detailed description and specific examples, while indicating preferred embodiments of the invention, are given by way of illustration only, since various changes and modifications within the spirit and scope of the invention will become apparent to those skilled in the art from this detailed description.

Brief description of the drawings

Other characteristics and advantages of the present invention will become more apparent on reading the following description given by way of non-limiting indication and with reference to the accompanying drawings, in which:

- Figure 1 shows an example of a technical drawing;
- Figure 2 shows an example of the information block in a drawing of the kind shown in Figure 1;
- Figure 3 shows the general structure of the hardware of apparatus for recognizing and indexing documents in accordance with the invention;
- Figure 4 is a flow chart explaining the operation of the Figure 3 apparatus when recognizing and indexing the drawing of Figure 1;
- Figure 5 is a flow chart showing greater detail of the function for searching and identifying a box in the block of Figure 2;
- Figure 6A shows a first search zone incorporating a portion of the box to be identified;
- Figures 6B and 6C are projection profiles obtained from the search zone of Figure 6A;
- Figure 7A shows a second search zone incorporating a larger portion of the box to be identified;
- Figures 7B and 7C are projection profiles obtained from the search zone of Figure 7A;
- Figure 8A shows a third search zone that fully contains the box to be identified; and

- Figures 8B and 8C are projection profiles obtained from the search zone of Figure 8A.

Detailed description of a preferred embodiment

As shown in Figures 1 and 2, a technical or industrial drawing such as a sheet 10 essentially comprises the drawing itself 12 and an information block 14 made up of a plurality of rectangular boxes of various sizes.

Most of these various boxes contain particular data (i.e., pieces of information) that are not all equally suitable for indexing a technical drawing. This applies, for example, to the data (information) specifying the projection, the scale, or the format of the drawing. Data that are important for indexing include in general at least a first box 16 containing a number identifying the drawing, a second box 18 containing the title of the drawing, and a third box 20 specifying who drew the drawing. Naturally, these three data should not be considered in any way as being limiting, and it is equally possible to envisage also taking account of the date of its most recent update available in a fourth box 22 or its page number which is to be found in a fifth box 24, etc.

Figure 3 shows hardware architecture that can be included in a computer system that is able to perform the method of the invention for recognizing and indexing documents of the type shown in Figure 1.

This computer system comprises firstly a digitizer or scanner 30 for scanning documents (specifically drawing sheets) that are subsequently to be indexed. The scanner is connected to a computer or a microcomputer of conventional type 32 provided with conventional software 100 for scanning purposes. A first database 34 also connected to the computer 32 serves to store documents scanned in this way. It will be observed that depending on the internal storage capacity of the computer 32 and the volume of the data corresponding to the documents to be scanned, this first database 34 can either be external, as shown, or else accommodated directly internally inside the computer 32. The computer 32 naturally includes software 110 for controlling this first database 34 (creating it, consulting it, modifying it).

To index documents in the first database 34, provision is made for the computer 32 also to have OCR software 120 of conventional type for recognizing and identifying certain particular elements of these documents. Nevertheless, such OCR software 120 is controlled by specific software 130 in association with

a second database 38 containing characterization data, enabling these documents to be processed in particularly simple and fast manner.

In the invention, this recognition is performed only within determined zones of the documents, and more particularly for a technical drawing, only in boxes of its information block that have been located by the user using a pointer device or member 36 of the computer such as a mouse, a track ball, or any other equivalent device (including the user's own finger if a touch-sensitive screen is used), enabling any arbitrary point P within the box to be designated. In addition, after the designation operation has been performed, and in order to further improve processing, the software 130 can optionally ask the user to define the type of data that is to be recognized in the box that has been designated, for example a string of numerical characters (for the identification number) or a string of alphanumerical characters (for the title or the name of the author, for example).

The method implemented in the above apparatus is illustrated in Figure 4 and thus follows the following steps. After a first document has been scanned in a first step 200 by the scanner 30 associated with the software 100, the image of the document is stored temporarily in a second step 210 in the memory of the computer 32 and possibly simultaneously it is displayed on the display screen of the computer (when necessary after performing a magnification or "zoom" operation). If the processing software 130 cannot identify the type of document that has been scanned on the basis of the data from the characterization database 38 (test in step 220), then this identification is performed during the following steps of the process, and in particular a step 230 is performed initially using the pointing member 36 associated with its software 130 whereby the user designates a point P in a first predetermined zone of the document, e.g. the box 16 in the information block 14 of the drawing that contains the identification number of the drawing. Optionally, and as shown in dashed lines in step 240, the user can then specify the type of character to be recognized in this box. This indication can serve to restrict the choice of characters to be recognized (e.g. only the digits 0 to 9), thereby improving the subsequent OCR step. Once this point has been designated (with its coordinates then being determined relative to a predetermined origin point), a new step 250 is performed in which the box containing the point P is searched for and identified (i.e. the boundary lines of the box are searched for and identified as explained in greater detail with

reference to Figure 5), and once the box has been identified (e.g. with the outline of the box being displayed at increased brightness or in another color) its characterization elements are stored in the second database 38 in a step 260 (the dimensions of the box and the position of its center are also stored), and in the immediately following step 270 OCR is performed conventionally on the characters in said box using conventional software means 120, with the end of this recognition operation being marked by the computer returning control to the user, for example.

The above five steps 230, optional 240, 250, 260, and 270 are then repeated for a second determined zone, and then another, until the document has been fully identified, i.e. until the software 110 has taken account of all of the zones necessary for indexing the document as previously determined depending on the use that is to be made thereof. Once this operation has been performed, a new step 280 is performed in which the scanned image and the OCR recognized character are stored in the first database 34. All of the preceding steps are optionally repeated for a second type of document, and so on until there are no more documents to be scanned and indexed. Thereafter, the first database 34 can be consulted by the software 110 which can serve conventionally to give access to each of the documents in the database as a function of criteria selected by a user and corresponding to one or more of the initially indicated indexing elements.

An important point is that the above designation operations are performed only when indexing a first document of a given type, since providing the following documents for processing are of the same type, then the test in step 220 obtains a "yes" answer and there is no longer any need to point at the same zones carrying the various items required for indexing. Since the software 130 can store the coordinates of the boxes in the characterization database 38 once they are initially designated, it then suffices merely to search for the same boxes in the following documents starting from the origin point (with resemblance being tested over the area of the box and with a certain amount of tolerance as explained with reference to Figure 5), and once each box has been identified, the content thereof is analyzed automatically by OCR without any prior designation of any point whatsoever in the boxes.

It will thus readily be understood that the method of the invention is particularly fast and effective since for a set of similar documents, once a given

type of document has been identified for the first time during which user intervention is indispensable, the following documents can continue to be identified automatically without the user taking any further action. On each occasion, OCR is applied only to those elements that are necessary for indexing the documents and not on the entire document as has been the case in the background art.

It will also be observed that "one by one" scanning as described above (one document after another) can be replaced by scanning a batch or by scanning all of a set of documents to be processed (i.e. automatically and storing the corresponding scanned images in the computer), with the identification and OCR steps being performed subsequently on each of the documents in the set in succession after the initial scanning operation has been completed.

Figure 5 shows the various operations performed by the search subprogram implemented in the software 130 for identifying a box as determined solely by the user designating a point P in the box. These operations are based on applying a shape search algorithm such as a projection algorithm or a Hough transform (for round shapes). Specifically, a particular application of a conventional projection algorithm is performed which includes counting the number of pixels present in each vertical and horizontal line of an image, and on the basis of these count numbers, in finding the horizontal and vertical lines in the image of the box by X and Y projection profiles (where the lines are determined by the peaks in said projection profiles). This algorithm has the advantage of providing a very high signal-to-noise ratio since the presence of any "hole" in a line (i.e. a mixing pixel) has little effect on the height of the peak, and similarly if the line slopes somewhat it has little effect on the position of the peak.

Nevertheless, in the invention, this projection algorithm is not applied to the entire document but only to a determined zone thereof (of area S_i defined in a first step 300) that is defined around the point P designated during the pointing step 220. Thus, assuming that this search zone contains the box to be recognized in full, it suffices merely to project (step 310) all of the vertical lines to the right of the point P in order to find the right side of the box (it will be where the peak (step 320) is greatest or greater than a given threshold). The same is done with the vertical lines on the left of the point for the left side of the box and with the horizontal lines above and below the point to find respectively the top

and bottom sides of the box (iteration via step 330). Nevertheless, in practice, this initial search zone will either lie within the box to be identified or it will overlap it (see for example area S1 in Figure 6A), so it is therefore appropriate to increase the area of this zone progressively (in successive determined steps) until it covers the box completely, thereby enabling it to be identified (see area S3 in Figure 8A). On each occasion, the projection algorithm (step 310) is applied. Identification comes to an end (test in step 330) when for two successive areas the positions of the projection peaks determined in the preceding step 320 remain the same. The coordinates of the box that has been found are then stored in a following step 340 so as to be used subsequently for automatic recognition of the following documents. An example of an implementation of the algorithm is shown with reference to Figures 6A to 8C which show the process implemented for identifying the box 18 that contains information for indexing, by way of example.

In the example, it is assumed that the user has clicked on the extreme lower right of the drawing 12 of Fig. 1, namely the box 14 of Figs. 1-2, in particular box 18. The software 130 then can create a first rectangular search zone of area S1 around this point, as shown in Figure 6A, which zone contains a right vertical side 400 and top and bottom portions 402 and 404 of the box to be identified. Applying the projection algorithm to this first search zone leads to the horizontal and vertical projections of Figures 6B and 6C. Figure 6B clearly shows two peaks 412 and 414 corresponding to the respective horizontal sides 402 and 404, and Figure 6C shows a single peak 410 corresponding to the vertical side 400. This initial analysis does not enable the box 18 to be analyzed, so a second search zone of area S2 is then examined automatically, and as shown in Figure 7A this area still contains the right vertical side 400 and portions, albeit longer portions, of the two horizontal sides 402, 404. The results of the horizontal and vertical projection algorithms are shown in Figures 7B and 7C. There can be seen the peaks 410, 412, 414 together with other peaks 418 and 420 which are more or less pronounced depending on how much of the data (information) "FLANK" appears in the horizontal projection and in the vertical projection. Finally, since this second application of the algorithm still does not enable the box 18 to be identified completely, a third search zone of area S3 is defined automatically which this time covers the entire box 18 (see Figure 8A), and in particular covers its horizontal side 402 and 404 in full together with its

left vertical side 406. The horizontal projection that results from the corresponding algorithm is shown in Figure 8B which has two peaks 412 and 414 corresponding to the two horizontal sides 402 and 404. However, the vertical projection now shows up, in addition to the series of peaks 420, not only the peak 410 corresponding to the right side 400 of the box 18, but also a new peak 416 corresponding to the left side 406 of the box, thus enabling the box 18 to be identified in full.

It is important to observe that although the method and the apparatus of the invention are described essentially in terms of recognizing and indexing technical drawings, it is naturally quite possible to envisage implementing the method for other types of documents, and in particular a most advantageous application lies in recognizing and indexing forms, e.g. of the order type (in particular for mail order) or indeed operations sheets. At present, processing such forms requires them to be characterized in advance by way of special symbols located at special locations on the forms, which symbols then enable the type of the form to be identified automatically. Under such circumstances, characterizing a form is a process that is lengthy and complex and can only be justified when a large quantity of similar documents need scanning.

With the present invention, this stage of prior characterization disappears and is replaced by a step of designating/identifying only those boxes of the form that are to be processed.

Thus, the method of identification is particularly fast (which is important when only a few technical drawings or forms are to be processed), simple, and can be performed by any operator even if not highly qualified. Furthermore, it is stable against any input noise that might result from the scanned documents being moved.

The invention being thus described, it will be obvious that the same may be varied in many ways. Such variations are not to be regarded as a departure from the spirit and scope of the invention, and all such modifications as would be obvious to one skilled in the art are intended to be included within the scope of the following claims.
